

Exploiting the Depmap cancer dependency data using the depmap R package

Theo Killian¹ and Laurent Gatto¹

¹Computational Biology and Bioinformatics Unit, de Duve Institute, UCLouvain, Brussels, Belgium

Abstract

The `depmap` package facilitates access in the R environment to the data from the Depmap project, a multi-year collaborative effort by the Broad Institute and Wellcome Sanger Institute, mapping genetic and chemical dependencies and other molecular biological measurements of over 1700 cancer cell lines. The `depmap` package formats this data for use of popular R data analysis and visualizing tools such as `dplyr` and `ggplot2`. In addition, the `depmap` package utilizes ExperimentHub, storing versions of the Depmap data accessible from the Cloud, which may be selectively downloaded, providing a reproducible research framework to support exploiting this data. This paper describes a workflow demonstrating how to access and visualize the Depmap data in R using this package.

Keywords

cancer, cancer dependency, Depmap, ExperimentHub, data mining, reproducible research, Bioconductor

Introduction

The consequences of genomic alterations of cancer cells on the molecular biological landscape of the cell may result in differential vulnerabilities, or “dependencies” compared to those of healthy cells. An example of genetic dependency is a gene not necessary for the survival in healthy cells, but essential for the vitality of particular cancer cell line. However, the exact biological nature of many genetic dependencies of cancer are not completely understood [1]. A map that illustrates the relationships between the genetic features of cancer and those of cancer dependencies is therefore desirable. The Cancer Dependency Map or “Depmap”, a collaborative initiative between the Broad Institute and the Wellcome Sanger Institute, aims to map genetic dependencies in a broad range of cancer cell lines. Hundreds of cancer cell lines have been selected to be tested in this effort, intended to mirror the distribution of various cancer diseases in the general population. The stated aim of the Depmap Project is developing a better picture of the molecular biology workings of cancer and the exploiting this knowledge to develop new therapies in precision cancer medicine [2].

The Depmap initiative is, as of the date of this publication, an ongoing project, with new data releases of select datasets every 90 days. As of the most current 20Q1 Depmap release, 1775 human cancer cell lines have been mapped for dependencies [2]. The Depmap project utilizes CRISPR gene knockout as the primary method to map genomic dependencies in cancer cell lines [2, 3, 4, 5]. The resulting genetic dependency score displayed in the Depmap data is calculated from the observed log fold change in the amount of shRNA detected in tested cancer cell population after gene knockout [6, 7]. To correct for potential off-target effects of gene knockout in overestimating dependency with CRISPR, the Depmap initiative utilized the CERES algorithm to moderate the final dependency score estimation [3]. It should be noted that due to advancements in the CERES algorithm to account for seed effects, the RNAi dependency has been rendered redundant, and further data releases for this dependency measurement have been discontinued as of the 19Q3 release [2, 4]. In addition genomic dependency measurements of cancer cell lines, chemical dependencies were also measured by the Depmap PRISM viability screens that as of the 20Q1 release, tested 4,518 compounds against 578 cancer cell lines [8, 2]. The Depmap project has also compiled additional datasets detailing molecular biological characterization of cancer cell lines, such as genomic copy number, Reverse Phase Protein Array (RPPA) data, TPM gene expression data for protein coding genes and genomic mutation data. These datasets are updated quarterly on a release schedule and are publically available under CC BY 4.0 licence [2].

A table of the most recent datasets available for the `depmap` package (as of 20_Q1 release) is displayed in table 1.

The `depmap` Bioconductor package was created in order to maximally exploit these rich datasets and to aide reproducible research, by importing the data into the R environment. The value added by the `depmap` Bioconductor package includes cleaning and converting all datasets to the long format tibbles [9], as well as adding the unique key `depmap_id` for all data tables. The addition of the the unique key `depmap_id` makes features more comparable, and facilitates the use of common R packages such as `dplyr` [10] and `ggplot2` [11].

As new Depmap datasets are released on a quarterly basis, it is not feasible to include all dataset files in binary directly within the directory of the `depmap` R package. To keep the package lightweight, the `depmap` package utilizes and fully depends on the ExperimentHub package [12] to store and retrieve all versions of the Depmap data (starting from 19Q1 through 20Q1) in the Cloud using AWS. The `depmap` package contains accessor functions to directly download and cache the most current datasets from the Cloud into the local R environment. Specific datasets (such as datasets from older releases), which can be downloaded separately, if desired. The `depmap` package was designed to enhance reproducible research by ensuring datasets from all releases will remain available in this manner. The `depmap` R package is available as part of Bioconductor at: <https://bioconductor.org/packages/depmap>.

Table 1. Datasets available the depmap package. The 'Release' column indicates the most recent available release.

Dataset	Description	Dimensions	Coverage	Release
rnai	(DEMETER2) Batch and off-target corrected RNAi gene knockdown dependency data	17309 genes, 712 cancer cell lines	31 primary diseases and 31 lineages	Aug 7 2019
drug	Drug sensitivity data for cancer cell lines derived from logfold change values relative to DMSO	4686 compounds, 578 cell lines	23 primary diseases and 25 lineages	Aug 7 2019
crispr	(CERES) Batch and off-target corrected CRISPR-Cas9 gene knockout dependency data	18333 genes, 739 cell lines	29 primary diseases and 26 lineages	Feb 20 2020
copyNumber	WES log copy number data	27639 genes, 1713 cell lines	35 primary diseases and 36 lineages	Feb 20 2020
TPM	CCLE TPM RNAseq gene expression data for protein coding genes	19144 genes, 1270 cancer cell lines	32 primary diseases and 34 lineages	Feb 20 2020
mutationCalls	Merged mutation calls (for coding region, germline filtered) and includes data	18802 genes, 1697 cell lines	35 primary diseases and 36 lineages	Feb 20 2020
metadata	Metadata for cell lines in the 20Q1 DepMap release	1775 cell lines	35 primary diseases and 37 lineages	Feb 20 2020

Use cases

Dependency scores are the features of primary interest in the Depmap Project datasets. These measurements can be found in datasets `crispr` and `rnai`, which contain information on genetic dependency, as well as the dataset `drug_sensitivity`, which contains information pertaining to chemical dependency. The genetic dependency can be interpreted as an expression of how vital a particular gene for a given cancer cell line. For example, a highly negative dependency score is derived from a large negative log fold change in the population of cancer cells after gene knockout or knockdown, implying that a given cell line is highly dependent on that knocked out gene. Genes that possess highly negative dependency scores may be interesting targets for research in cancer medicine. In this workflow, we will describe exploring and visualizing several Depmap datasets, including those that contain information on genetic dependency.

Below, we start by loading the packages need to run this workflow.

```
library("depmap")
library("ExperimentHub")
library("dplyr")
library("ggplot2")
library("stringr")
```

The depmap datasets are too large to be included into a typical package, therefore these data are stored in the Cloud. There are two ways to access the depmap datasets. The first such way calls on dedicated accessor functions that download, cache and load the latest available dataset into the R workspace. Examples for all available data are shown below:

```
rnai <- depmap_rnai()
crispr <- depmap_crispr()
copyNumber <- depmap_copyNumber()
TPM <- depmap_RPPA()
RPPA <- depmap_TPM()
metadata <- depmap_metadata()
mutationCalls <- depmap_mutationCalls()
drug_sensitivity <- depmap_drug_sensitivity()
```

Alternatively, specific dataset (from any available release) can be accessed through Bioconductor's `ExperimentHub`. The `ExperimentHub()` function creates an `ExperimentHub` object, which can be queried for specific terms. The list of datasets available that correspond to the query, `depmap` are shown below:

```
## create ExperimentHub query object
eh <- ExperimentHub()
query(eh, "depmap")
```

```
## ExperimentHub with 32 records
## # snapshotDate(): 2020-04-27
## # $dataprovder: Broad Institute
## # $species: Homo sapiens
## # $rdataclass: tibble
## # additional mcols(): taxonomyid, genome, description,
## #   coordinate_1_based, maintainer, rdatadateadded, preparerclass, tags,
## #   rdatapath, sourceurl, sourcetype
## # retrieve records with, e.g., 'object[["EH2260"]]'
##
##           title
## EH2260 | rnai_19Q1
## EH2261 | crispr_19Q1
## EH2262 | copyNumber_19Q1
## EH2263 | RPPA_19Q1
## EH2264 | TPM_19Q1
## ...    ...
## EH3290 | crispr_20Q1
## EH3291 | copyNumber_20Q1
## EH3292 | TPM_20Q1
## EH3293 | mutationCalls_20Q1
## EH3294 | metadata_20Q1
```

Specific datasets are downloaded, cached and loaded into the workspace as tibbles by selecting each dataset by their unique EH numbers. Shown below, datasets from the 19_Q3 release are downloaded in this way.

```
## download and cache required datasets
metadata <- eh[["EH3086"]]
crispr <- eh[["EH3081"]]
TPM <- eh[["EH3084"]]
mutationCalls <- eh[["EH3085"]]
copyNumber <- eh[["EH3082"]]
```

By importing the depmap data into the R environment, the data can be mined more effectively utilizing R data manipulation tools. For example, if one was interested in researching soft tissue sarcomas and wanted to search all such cancer cell lines for the gene with the greatest dependency, one could accomplish this task by using functions from the dplyr package. Below, the crispr dataset is selected for cell lines with "SOFT_TISSUE" in the CCLE name, and displaying a list of the highest dependency scores.

```
## list of dependency scores
crispr %>%
  dplyr::select(cell_line, gene_name, dependency) %>%
  dplyr::filter(stringr::str_detect(cell_line, "SOFT_TISSUE")) %>%
  dplyr::arrange(dependency)
```

```
## # A tibble: 586,656 x 3
##   cell_line      gene_name dependency
##   <chr>          <chr>         <dbl>
## 1 RH30_SOFT_TISSUE RAN             -3.19
## 2 SCS214_SOFT_TISSUE RPL37          -2.85
## 3 RH30_SOFT_TISSUE BUB3            -2.83
## 4 RH30_SOFT_TISSUE C1orf109         -2.82
## 5 SCS214_SOFT_TISSUE POLR2J          -2.79
## 6 RH30_SOFT_TISSUE PSMD7            -2.75
## 7 SCS214_SOFT_TISSUE SOD1            -2.73
## 8 RH30_SOFT_TISSUE SS18L2          -2.69
## 9 SCS214_SOFT_TISSUE RNPC3          -2.69
## 10 RH30_SOFT_TISSUE CHAF1B          -2.68
## # ... with 586,646 more rows
```

The gene RPL14 appears several times in the top dependencies scores, and may make an interesting candidate target. Figure 1 displays the crispr data as a histogram showing the distribution of dependency scores for gene RPL14. The red dotted line signifies the mean dependency score for that gene, while the blue dotted line signifies the global mean dependency score for all crispr measurements.

Figure 1. Histogram of CRISPR dependency scores for gene RPL14.

```
mean_crispr_dep <- crispr %>%
  dplyr::select(gene_name, dependency) %>%
  dplyr::filter(gene_name == "RPL14")

crispr %>%
  dplyr::select(gene, gene_name, dependency) %>%
  dplyr::filter(gene_name == "RPL14") %>%
  ggplot(aes(x = dependency)) + geom_histogram() +
  geom_vline(xintercept = mean(mean_crispr_dep$dependency, na.rm = TRUE),
    linetype = "dotted", color = "red") +
  geom_vline(xintercept = mean(crispr$dependency, na.rm = TRUE),
    linetype = "dotted", color = "blue")
```

A more complex plot of the `crispr` data, is shown below 2. Visualizing this data involves plotting the distribution of dependency scores for gene RPL14 for each major type of cancer, while highlighting the qualitative nature of mutations of this gene in such cancer cell lines (e.g. if such mutations are damaging or conserved, etc.). Notice that the plot above 1 reflects the same overall distribution in two dimensions.

```
meta_crispr <- metadata %>%
  dplyr::select(depmap_id, lineage) %>%
  dplyr::full_join(crispr, by = "depmap_id") %>%
  dplyr::filter(gene_name == "RPL14") %>%
  dplyr::full_join((mutationCalls %>%
```

Figure 2. Plot of CRISPR dependency scores for gene RPL14 by lineage.

```
dplyr::select(depmap_id, entrez_id,
              is_cosmic_hotspot,
              var_annotation),
by = c("depmap_id", "entrez_id"))

meta_crispr %>%
  ggplot(aes(x = dependency, y = lineage)) +
  geom_point(alpha = 0.4, size = 0.5) +
  geom_point(data = subset(meta_crispr,
                          var_annotation == "damaging"),
            color = "red") +
  geom_point(data = subset(meta_crispr,
                          var_annotation == "other non-conserving"),
            color = "blue") +
  geom_vline(xintercept = mean(meta_crispr$dependency, na.rm = TRUE),
            linetype = "dotted", color = "red") +
  geom_vline(xintercept = mean(crispr$dependency, na.rm = TRUE),
            linetype = "dotted", color = "blue")
```

Many cancer phenotypes are the result of changes in gene expression [13, 14, 15]. The extensive coverage of the depmap data affords visualization of genetic expression patterns across many major types of cancer. Figure 3 below shows a boxplot illustrating expression values for gene RPL14 by lineage:

Figure 3. Boxplot of TPM expression values for gene RPL14 by lineage.

```
metadata %>%
  dplyr::select(depmap_id, lineage) %>%
  dplyr::full_join(TPM, by = "depmap_id") %>%
  dplyr::filter(gene_name == "RPL14") %>%
  ggplot(aes(x = lineage, y = expression, fill = lineage)) +
  geom_boxplot(outlier.alpha = 0.1) +
  theme(axis.text.x = element_text(angle = 45, hjust = 1)) +
  theme(legend.position = "none")
```

Elevated gene expression and genetic dependency in cancer cell lines have been reported in literature [1, 7]. Therefore, genes with elevated gene expression and high genetic dependency may present especially interesting research targets. Figure 4 shows a plot of expression versus CRISPR gene dependency for Rhabdomyosarcoma. The red vertical line represents the average expression for this form of cancer, while the horizontal line represents the average dependency for this cancer type.

```
sarcoma <- metadata %>%
  dplyr::select(depmap_id, cell_line, primary_disease, subtype_disease) %>%
  dplyr::filter(primary_disease == "Sarcoma",
    subtype_disease == "Rhabdomyosarcoma")

crispr_sub <- crispr %>%
  dplyr::select(depmap_id, gene, gene_name, dependency)
```

```

tpm_sub <- TPM %>%
  dplyr::select(depmap_id, gene, gene_name, expression)

sarcoma_dep <- sarcoma %>%
  dplyr::left_join(crispr_sub, by = "depmap_id") %>%
  dplyr::select(-cell_line, -primary_disease,
               -subtype_disease, -gene_name)

sarcoma_exp <- sarcoma %>%
  dplyr::left_join(tpm_sub, by = "depmap_id")

sarcoma_dat_exp <- dplyr::full_join(sarcoma_dep, sarcoma_exp,
                                   by = c("depmap_id", "gene")) %>%
  dplyr::filter(!is.na(expression))

```

```

sarcoma_dat_exp %>%
ggplot(aes(x = dependency, y = expression)) +
  geom_point(alpha = 0.4, size = 0.5) +
  geom_vline(xintercept = mean(sarcoma_dat_exp$dependency, na.rm = TRUE),
             linetype = "dotted", color = "red") +
  geom_hline(yintercept = mean(sarcoma_dat_exp$expression, na.rm = TRUE),
             linetype = "dotted", color = "red") +
  ggtitle("Scatterplot of CRISPR dependency vs expression values for gene") +
  theme(axis.text.x = element_text(angle = 45))

```

Genes with the highest dependency scores and highest TPM gene expression are found in the upper left section of the plot above 4. Almost all of the genes with the highest dependency scores display increased expression.

```

sarcoma_dat_exp %>%
  dplyr::select(cell_line, gene_name, dependency, expression) %>%
  dplyr::arrange(dependency, expression)

```

```

## # A tibble: 95,720 x 4
##   cell_line      gene_name dependency expression
##   <chr>          <chr>      <dbl>      <dbl>
## 1 SCRCRM2_SOFT_TISSUE RAN          -2.44        9.89
## 2 SCRCRM2_SOFT_TISSUE SNRPD1         -2.30        7.99
## 3 SCRCRM2_SOFT_TISSUE POLR2L         -2.26        6.09
## 4 SCRCRM2_SOFT_TISSUE PSMA3          -2.23        7.58

## 6 SCRCRM2_SOFT_TISSUE ATP6V1B2        -2.19        5.44
## 7 SCRCRM2_SOFT_TISSUE CHAF1B         -2.17        2.22
## 8 SCRCRM2_SOFT_TISSUE HSPE1          -2.17        9.23
## 9 SCRCRM2_SOFT_TISSUE RRM2           -2.16        6.59
## 10 SCRCRM2_SOFT_TISSUE RPL12          -2.15       12.1
## # ... with 95,710 more rows

```

Changes in genomic copy number may also play a role in some cancer phenotypes [3, 16, 17]. The depmap data allows the display of log genomic copy number for across many cancer lineages. Figure 5 shows such a plot for gene RPL14 for each major type of cancer lineage:

```

metadata %>%
  dplyr::select(depmap_id, lineage) %>%
  dplyr::full_join(copyNumber, by = "depmap_id") %>%
  dplyr::filter(gene_name == "RPL14") %>%
  ggplot(aes(x = lineage, y = log_copy_number, fill = lineage)) +
  geom_boxplot(outlier.alpha = 0.1) +
  theme(axis.text.x = element_text(angle = 45, hjust = 1)) +
  theme(legend.position = "none")

```

Figure 4. Expression vs crispr gene dependency for Rhabdomyosarcoma.

Figure 5. Boxplot of log copy number for gene RPL14 by lineage

Discussion and outlook

We hope that this package will be used by cancer researchers to dig deeper into the Depmap data and to support their research. Additionally, we highly encourage future depmap users to combine depmap data with other datasets of interest, such as TCGA and CCLE.

The depmap R package will continue to be maintained in line with the biannual Bioconductor release, in addition to quarterly releases of Depmap data.

We welcome feedback and questions from the community. We also highly appreciate contributions to the code in the form of pull requests.

Software availability

All packages used in this workflow are available from the Comprehensive R Archive Network (<https://cran.r-project.org>) or Bioconductor (<http://bioconductor.org>). The specific version numbers of R and the packages used are shown below.

To install the depmap package:

```
BiocManager::install('depmap')
